Chapter 8.
Classification: Basic Concepts

Meng Jiang

CS412 Summer 2017:

Introduction to Data Mining

### Classification: Basic Concepts

- Classification: Basic Concepts
- Decision Tree Induction
- Bayes Classification Methods
- Model Evaluation and Selection
- Techniques to Improve Classification Accuracy: Ensemble Methods

### Supervised vs. Unsupervised Learning

- Supervised learning (classification)
  - Supervision: The training data (observations, measurements, etc.) are accompanied by labels indicating the class of the observations
  - New data is classified based on the training set
- Unsupervised learning (clustering)
  - The class labels of training data is unknown
  - Given a set of measurements, observations, etc. with the aim of establishing the existence of classes or clusters in the data

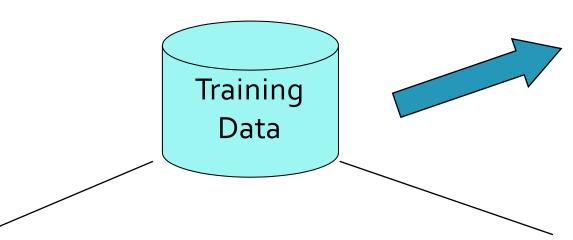

## Prediction Problems: Classification vs. Numeric Prediction

- Classification
  - predicts categorical class labels (discrete or nominal)
  - classifies data (constructs a model) based on the training set and the values (class labels) in a classifying attribute and uses it in classifying new data
- Numeric Prediction
  - models continuous-valued functions, i.e., predicts unknown or missing values
- Typical applications
  - Credit/loan approval:
  - Medical diagnosis: if a tumor is cancerous or benign
  - Fraud detection: if a transaction is fraudulent
  - Web page categorization: which category it is

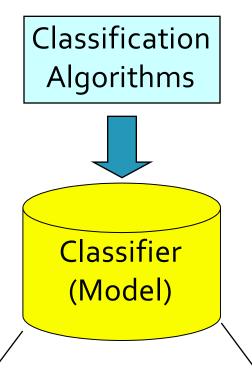

## Classification: A Two-Step Process

- Model construction: describing a set of predetermined classes
  - Each tuple/sample is assumed to belong to a predefined class, as determined by the class label attribute
  - The set of tuples used for model construction is training set
  - Model: represented as classification rules, decision trees, or mathematical formulae
- **Model usage**: for classifying future or unknown objects
  - Estimate accuracy of the model
    - The known label of test sample is compared with the classified result from the model
    - Accuracy: % of test set samples that are correctly classified by the model
    - Test set is independent of training set (otherwise overfitting)
  - If the accuracy is acceptable, use the model to classify new data
- Note: If the test set is used to select/refine models, it is called validation (test) set or development test set

### (1) Model Construction

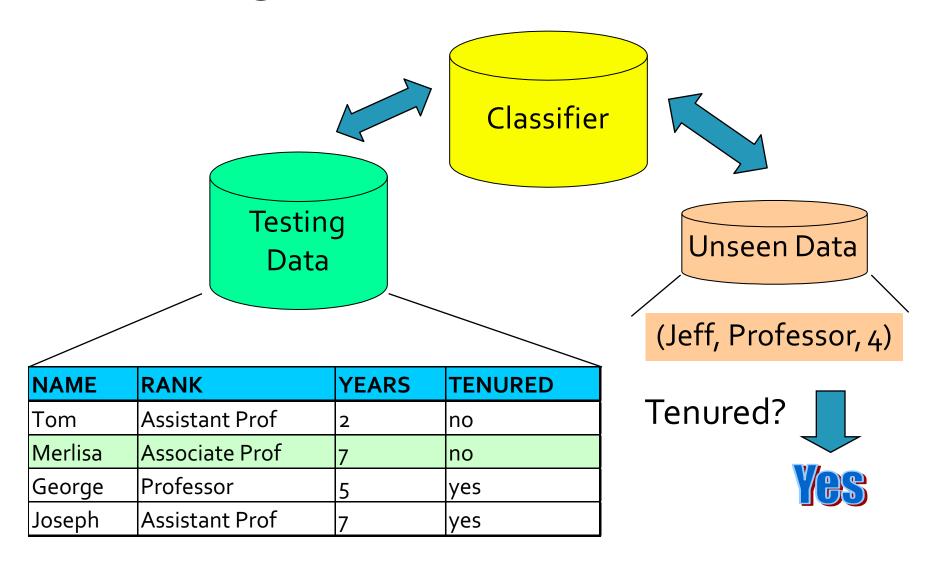

NAME RANK		YEARS	TENURED
Mike	Assistant Prof	3	no
Mary	Assistant Prof	7	yes
Bill	Professor	2	yes
Jim	Associate Prof	7	yes
Dave	ave Assistant Prof		no
Anne Associate Prof		3	no

IF rank = 'professor' OR years > 6 THEN tenured = 'yes'

## (2) Using the Model in Prediction

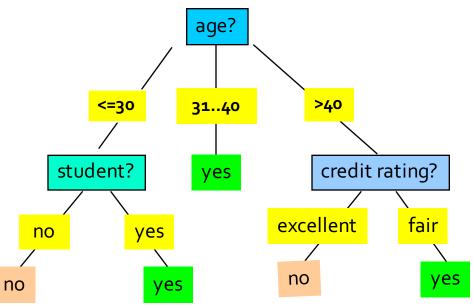

### Classification: Basic Concepts

- Classification: Basic Concepts
- Decision Tree Induction
- Bayes Classification Methods
- Model Evaluation and Selection
- Techniques to Improve Classification Accuracy: Ensemble Methods

### Decision Tree Induction: An Example

- Training data set: Buys\_computer
- The data set follows an example of Quinlan's ID3 (Playing Tennis)
- Resulting tree:

age	income	student	credit_rating	buys_computer
<=30	high	no	fair	no
<=30	high	no	excellent	no
3140	high	no	fair	yes
>40	medium	no	fair	yes
>40	low	yes	fair	yes
>40	low	yes	excellent	no
3140	low	yes	excellent	yes
<=30	medium	no	fair	no
<=30	low	yes	fair	yes
>40	medium	yes	fair	yes
<=30	medium	yes	excellent	yes
3140	medium	no	excellent	yes
3140	high	yes	fair	yes
>40	medium	no	excellent	no

### Algorithm for Decision Tree Induction

- Basic algorithm (a greedy algorithm)
  - Tree is constructed in a top-down recursive divide-and-conquer manner
  - At start, all the training examples are at the root
  - Attributes are categorical (if continuous-valued, they are discretized in advance)
  - Examples are partitioned recursively based on selected attributes
  - Test attributes are selected on the basis of a heuristic or statistical measure (e.g., information gain)
- Conditions for stopping partitioning
  - All samples for a given node belong to the same class
  - There are no remaining attributes for further partitioning—majority voting is employed for classifying the leaf
  - There are no samples left

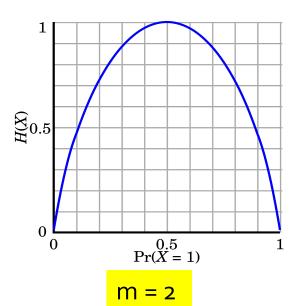

## **Brief Review of Entropy**

- Entropy (Information Theory)
  - A measure of uncertainty associated with a random number
  - Calculation: For a discrete random variable Y taking m distinct values  $\{y_1, y_2, ..., y_m\}$

$$H(Y) = -\sum_{i=1}^{m} p_i \log(p_i) \text{ where } p_i = P(Y = y_i)$$

- Interpretation
  - Higher entropy → higher uncertainty
  - Lower entropy → lower uncertainty
- Conditional entropy

$$H(Y|X) = \sum_{x} p(x)H(Y|X = x)$$

# Attribute Selection Measure: Information Gain (ID3/C4.5)

- Select the attribute with the highest information gain
- Let pi be the probability that an arbitrary tuple in D belongs to class C<sub>i</sub>, estimated by |C<sub>i, D</sub>|/|D|
- Expected information (entropy) needed to classify a tuple in D:  $Info(D) = -\sum_{i=1}^{m} p_i \log_2(p_i)$
- Information needed (after using A to split D into v partitions) to classify D:

$$Info_A(D) = \sum_{j=1}^{\nu} \frac{|D_j|}{|D|} \times Info(D_j)$$

Information gained by branching on attribute A

$$Gain(A) = Info(D) - Info_A(D)$$

### Attribute Selection: Information Gain

- Class P: buys\_computer = "yes"
- Class N: buys\_computer = "no"

$$Info(D) = I(9,5) = -\frac{9}{14}\log_2(\frac{9}{14}) - \frac{5}{14}\log_2(\frac{5}{14}) = 0.940$$

age	p <sub>i</sub>	n <sub>i</sub>	l(p, դ)
<=30	2	3	0.971
3140	4	O	o
>40	3	2	0.971

$Info_{age}(D) = \frac{3}{14}I(2,3) + \frac{4}{14}I(4,0)$	))
$+\frac{5}{14}I(3,2) = 0.694$	

$$\frac{5}{14}I(2,3)$$
 means "age <=30" has 5 out of 14 samples, with 2 yes'es and 3 no's.

Hence

$$Gain(age) = Info(D) - Info_{age}(D) = 0.246$$

$$Gain(income) = 0.029$$

$$Gain(student) = 0.151$$

$$Gain(credit \ rating) = 0.048$$

age	income	student	credit_rating	buys_computer
<=30	high	no	fair	no
<=30	high	no	excellent	no
3140	high	no	fair	yes
>40	medium	no	fair	yes
>40	low	yes	fair	yes
>40	low	yes	excellent	no
3140	low	yes	excellent	yes
<=30	medium	no	fair	no
<=30	low	yes	fair	yes
>40	medium	yes	fair	yes
<=30	medium	yes	excellent	yes
3140	medium	no	excellent	yes
3140	high	yes	fair	yes
>40	medium	no	excellent	no

# Computing Information-Gain for Continuous-Valued Attributes

- Let attribute A be a continuous-valued attribute
- Must determine the best split point for A
  - Sort the value A in increasing order
  - Typically, the midpoint between each pair of adjacent values is considered as a possible split point
    - $(a_i+a_{i+1})/2$  is the midpoint between the values of  $a_i$  and  $a_{i+1}$
  - The point with the minimum expected information requirement for A is selected as the split-point for A
- Split:
  - D1 is the set of tuples in D satisfying A ≤ split-point, and D2 is the set of tuples in D satisfying A > split-point

### Gain Ratio for Attribute Selection (C4.5)

- Information gain measure is biased towards attributes with a large number of values
- C4.5 (a successor of ID3) uses gain ratio to overcome the problem (normalization to information gain)

$$SplitInfo_A(D) = -\sum_{j=1}^{\nu} \frac{|D_j|}{|D|} \times \log_2(\frac{|D_j|}{|D|})$$

- GainRatio(A) = Gain(A)/SplitInfo(A)
- EX.  $SplitInfo_{income}(D) = -\frac{4}{14} \times \log_2(\frac{4}{14}) \frac{6}{14} \times \log_2(\frac{6}{14}) \frac{4}{14} \times \log_2(\frac{4}{14}) = 1.557$ 
  - gain\_ratio(income) = 0.029/1.557 = 0.019
- The attribute with the maximum gain ratio is selected as the splitting attribute

# Gini Index (CART, IBM IntelligentMiner)

• If a data set D contains examples from n classes, gini index, gini(D) is defined as  $gini(D) = 1 - \sum_{n=0}^{n} n^2$ 

 $gini(D) = 1 - \sum_{j=1}^{n} p_j^2$ 

where  $p_i$  is the relative frequency of class j in D

• If a data set D is split on A into two subsets  $D_1$  and  $D_2$ , the gini index gini(D) is defined as

 $gini_A(D) = \frac{|D_1|}{|D|}gini(D_1) + \frac{|D_2|}{|D|}gini(D_2)$ 

Reduction in Impurity:

$$\Delta gini(A) = gini(D) - gini_A(D)$$

• The attribute provides the smallest  $gini_{split}(D)$  (or the largest reduction in impurity) is chosen to split the node (need to enumerate all the possible splitting points for each attribute)

### Computation of Gini Index

Ex. D has 9 tuples in buys\_computer = "yes" and 5 in "no"

$$gini(D) = 1 - \left(\frac{9}{14}\right)^2 - \left(\frac{5}{14}\right)^2 = 0.459$$

• Suppose the attribute income partitions D into 10 in  $D_1$ : {low, medium} and 4 in  $D_2$ 

$$\begin{aligned} & gini_{income \in \{low, medium\}}(D) = \left(\frac{10}{14}\right) & Gini(D_1) + \left(\frac{4}{14}\right) & Gini(D_2) = \frac{10}{14} \left(1 - \left(\frac{7}{10}\right)^2 - \left(\frac{3}{10}\right)^2\right) + \frac{4}{14} \left(1 - \left(\frac{2}{4}\right)^2 - \left(\frac{2}{4}\right)^2\right) \\ &= 0.443 \\ &= Gini_{income} \in \{high\}(D). \end{aligned}$$

Gini<sub>{low,high}</sub> is 0.458; Gini<sub>{medium,high}</sub> is 0.450. Thus, split on the {low,medium} (and {high}) since it has the lowest Gini index

- All attributes are assumed continuous-valued
- May need other tools, e.g., clustering, to get the possible split values
- Can be modified for categorical attributes

### Comparing Attribute Selection Measures

- The three measures, in general, return good results but
  - Information gain:
    - biased towards multivalued attributes

#### – Gain ratio:

 tends to prefer unbalanced splits in which one partition is much smaller than the others

#### – Gini index:

- biased to multivalued attributes
- has difficulty when # of classes is large
- tends to favor tests that result in equal-sized partitions and purity in both partitions

### Other Attribute Selection Measures

- CHAID: a popular decision tree algorithm, measure based on  $\chi^2$  test for independence
- <u>C-SEP</u>: performs better than info. gain and gini index in certain cases
- G-statistic: has a close approximation to  $\chi^2$  distribution
- <u>MDL (Minimal Description Length) principle</u> (i.e., the simplest solution is preferred):
  - The best tree as the one that requires the fewest # of bits to both (1) encode the tree, and (2) encode the exceptions to the tree
- Multivariate splits (partition based on multiple variable combinations)
  - CART: finds multivariate splits based on a linear comb. of attrs.
- Which attribute selection measure is the best?
  - Most give good results, none is significantly superior than others

## Overfitting and Tree Pruning

- Overfitting: An induced tree may overfit the training data
  - Too many branches, some may reflect anomalies due to noise or outliers
  - Poor accuracy for unseen samples
- Two approaches to avoid overfitting
  - Prepruning: Halt tree construction early-do not split a node if this would result in the goodness measure falling below a threshold
    - Difficult to choose an appropriate threshold
  - Postpruning: Remove branches from a "fully grown" tree—get a sequence of progressively pruned trees
    - Use a set of data different from the training data to decide which is the "best pruned tree"

## Classification in Large Databases

- Classification—a classical problem extensively studied by statisticians and machine learning researchers
- Scalability: Classifying data sets with millions of examples and hundreds of attributes with reasonable speed
- Why is decision tree induction popular?
  - relatively faster learning speed (than other classification methods)
  - convertible to simple and easy to understand classification rules
  - can use SQL queries for accessing databases
  - comparable classification accuracy with other methods
- RainForest (VLDB'98 Gehrke, Ramakrishnan & Ganti)
  - Builds an AVC-list (attribute, value, class label)

#### RainForest: A Scalable Classification Framework

- The criteria that determine the quality of the tree can be computed separately
  - Builds an AVC-list: AVC (Attribute, Value, Class\_label)
- **AVC-set** (of an attribute *X* )
  - Projection of training dataset onto the attribute X and class label where counts of individual class label are aggregated
- **AVC-group** (of a node *n* )
  - Set of AVC-sets of all predictor attributes at the node n

age	income	student	credit_rating	buys_computer
<=30	high	no	fair	no
<=30	high	no	excellent	no
3140	high	no	fair	yes
>40	medium	no	fair	yes
>40	low	yes	fair	yes
>40	low	yes	excellent	no
3140	low	yes	excellent	yes
<=30	medium	no	fair	no
<=30	low	yes	fair	yes
>40	medium	yes	fair	yes
<=30	medium	yes	excellent	yes
3140	medium	no	excellent	yes
3140	high	yes	fair	yes
>40	medium	no	excellent	no

#### AVC-set on Age

Age	Buy_Computer	
	yes	no
<=30	2	3
3140	4	0
>40	3	2

#### AVC-set on Student

student	Buy_Computer		
	yes	no	
yes	6	1	
no	3	4	

#### AVC-set on Income

income	Buy_Computer	
	yes	no
high	2	2
medium	4	2
low	3	1

#### AVC-set on *Credit\_Rating*

Credit	Buy_Computer		
rating	yes	no	
fair	6	2	
excellent	3	3	

### Classification: Basic Concepts

- Classification: Basic Concepts
- Decision Tree Induction
- Bayes Classification Methods
- Model Evaluation and Selection
- Techniques to Improve Classification Accuracy: Ensemble Methods

### Bayesian Classification: Why?

- <u>A statistical classifier</u>: performs *probabilistic prediction, i.e.,* predicts class membership probabilities
- Foundation: Based on Bayes' Theorem.
- <u>Performance:</u> A simple Bayesian classifier, naïve Bayesian classifier, has comparable performance with decision tree and selected neural network classifiers
- Incremental: Each training example can incrementally increase/decrease the probability that a hypothesis is correct — prior knowledge can be combined with observed data
- <u>Standard</u>: Even when Bayesian methods are computationally intractable, they can provide a standard of optimal decision making against which other methods can be measured

### Bayes' Theorem: Basics

- Total probability Theorem:  $P(B) = \sum_{i=1}^{M} P(B|A_i)P(A_i)$
- Bayes' Theorem:  $P(H|\mathbf{X}) = \frac{P(\mathbf{X}|H)P(H)}{P(\mathbf{X})} = P(\mathbf{X}|H) \times P(H)/P(\mathbf{X})$ 
  - Let X be a data sample ("evidence"): class label is unknown
  - Let H be a hypothesis that X belongs to class C
  - Classification is to determine P(H|X), (i.e., posteriori probability): the probability that the hypothesis holds given the observed data sample X
  - P(H) (prior probability): the initial probability
    - E.g., X will buy computer, regardless of age, income, ...
  - P(X): probability that sample data is observed
  - P(X|H) (likelihood): the probability of observing the sample X, given that the hypothesis holds
    - E.g., Given that **X** will buy computer, the prob. that X is 31..40, medium income

### Prediction Based on Bayes' Theorem

 Given training data X, posteriori probability of a hypothesis H, P(H|X), follows the Bayes' theorem

$$P(H|\mathbf{X}) = \frac{P(\mathbf{X}|H)P(H)}{P(\mathbf{X})} = P(\mathbf{X}|H) \times P(H)/P(\mathbf{X})$$

- Informally, this can be viewed as posteriori = likelihood x prior/evidence
- Predicts X belongs to  $C_i$  iff the probability  $P(C_i|X)$  is the highest among all the  $P(C_k|X)$  for all the k classes
- Practical difficulty: It requires initial knowledge of many probabilities, involving significant computational cost

# Classification is to Derive the Maximum Posteriori

- Let D be a training set of tuples and their associated class labels, and each tuple is represented by an n-D attribute vector  $\mathbf{X} = (x_1, x_2, ..., x_n)$
- Suppose there are m classes C<sub>1</sub>, C<sub>2</sub>, ..., C<sub>m</sub>.
- Classification is to derive the maximum posteriori, i.e., the maximal  $P(C_i|\mathbf{X})$
- This can be derived from Bayes' theorem

$$P(C_i|\mathbf{X}) = \frac{P(\mathbf{X}|C_i)P(C_i)}{P(\mathbf{X})}$$

Since P(X) is constant for all classes, only

$$P(C_i|\mathbf{X}) = P(\mathbf{X}|C_i)P(C_i)$$

needs to be maximized

### Naïve Bayes Classifier

A simplified assumption: attributes are conditionally independent (i.e., no dependence relation between attributes):

 $P(\mathbf{X} | C_i) = \prod_{k=1}^{n} P(x_k | C_i) = P(x_1 | C_i) \times P(x_2 | C_i) \times ... \times P(x_n | C_i)$ 

- This greatly reduces the computation cost: Only counts the class distribution
- If  $A_k$  is categorical,  $P(x_k|C_i)$  is the # of tuples in  $C_i$  having value  $x_k$  for  $A_k$  divided by  $|C_{i,D}|$  (# of tuples of  $C_i$  in D)
- If  $A_k$  is continous-valued,  $P(x_k|C_i)$  is usually computed based on Gaussian distribution with a mean  $\mu$  and standard deviation  $\sigma$

$$g(x,\mu,\sigma) = \frac{1}{\sqrt{2\pi}\sigma} e^{-\frac{(x-\mu)^2}{2\sigma^2}}$$

and  $P(x_k|C_i)$  is  $P(X|C_i) = g(x_k, \mu_{C_i}, \sigma_{C_i})$ 

# Naïve Bayes Classifier: Training Dataset

#### Class:

- C1:buys\_computer = 'yes'
- C2:buys\_computer = 'no'

#### Data to be classified:

X = (age <=30, Income = medium, Student = yes, Credit\_rating = Fair)</li>

ć	age	income	student	credit_rating	buys_computer
′ <	<=30	high	no	fair	no
<	<=30	high	no	excellent	no
(1)	3140	high	no	fair	yes
>	<b>&gt;</b> 40	medium	no	fair	yes
>	<b>&gt;</b> 40	low	yes	fair	yes
^	<b>&gt;</b> 40	low	yes	excellent	no
(1)	3140	low	yes	excellent	yes
<	<=30	medium	no	fair	no
<	<=30	low	yes	fair	yes
>	<b>&gt;</b> 40	medium	yes	fair	yes
<	<=30	medium	yes	excellent	yes
(1)	3140	medium	no	excellent	yes
(1)	3140	high	yes	fair	yes
>	<b>&gt;</b> 40	medium	no	excellent	no

## Naïve Bayes Classifier: An Example

- $P(C_i)$ :  $P(buys\_computer = "yes") = 9/14 = 0.643$  $P(buys\_computer = "no") = 5/14 = 0.357$
- Compute  $P(X|C_i)$  for each class

```
P(age = "<=30" | buys\_computer = "yes") = 2/9 = 0.222
P(age = "<= 30" | buys\_computer = "no") = 3/5 = 0.6
P(income = "medium" | buys_computer = "yes") = 4/9 = 0.444
P(income = "medium" | buys_computer = "no") = 2/5 = 0.4
P(student = "yes" | buys_computer = "yes) = 6/9 = 0.667
P(student = "yes" | buys\_computer = "no") = 1/5 = 0.2
P(credit_rating = "fair" | buys_computer = "yes") = 6/9 = 0.667
P(credit_rating = "fair" | buys_computer = "no") = 2/5 = 0.4
```

age	income	student	credit_rating	buys_computer
<=30	high	no	fair	no
<=30	high	no	excellent	no
3140	high	no	fair	yes
>40	medium	no	fair	yes
>40	low	yes	fair	yes
>40	low	yes	excellent	no
3140	low	yes	excellent	yes
<=30	medium	no	fair	no
<=30	low	yes	fair	yes
>40	medium	yes	fair	yes
<=30	medium	yes	excellent	yes
3140	medium	no	excellent	yes
3140	high	yes	fair	yes
>40	medium	no	excellent	no

X = (age <= 30, income = medium, student = yes, credit\_rating = fair)

$$P(X|C_i)$$
:  $P(X|buys\_computer = "yes") = 0.222 × 0.444 × 0.667 × 0.667 = 0.044  $P(X|buys\_computer = "no") = 0.6 × 0.4 × 0.2 × 0.4 = 0.019$$ 

$$P(X|C_i)*P(C_i): P(X|buys\_computer = "yes") * P(buys\_computer = "yes") = 0.028$$
  
 $P(X|buys\_computer = "no") * P(buys\_computer = "no") = 0.007$ 

Therefore, X belongs to class ("buys\_computer = yes")

# Avoiding the Zero-Probability Problem

 Naïve Bayesian prediction requires each conditional prob. be non-zero. Otherwise, the predicted prob. will be zero

$$P(X \mid C_i) = \prod_{k=1}^{n} P(x_k \mid C_i)$$

- Ex. Suppose a dataset with 1000 tuples, income=low (0), income= medium (990), and income = high (10)
- Use Laplacian correction (or Laplacian estimator)
  - Adding 1 to each case

Prob(income = low) = 1/1003 Prob(income = medium) = 991/1003 Prob(income = high) = 11/1003

 The "corrected" prob. estimates are close to their "uncorrected" counterparts

### Naïve Bayes Classifier: Comments

- Advantages
  - Easy to implement
  - Good results obtained in most of the cases
- Disadvantages
  - Assumption: class conditional independence, therefore loss of accuracy
  - Practically, dependencies exist among variables
    - E.g., hospitals: patients: Profile: age, family history, etc.
       Symptoms: fever, cough etc., Disease: lung cancer, diabetes, etc.
    - Dependencies among these cannot be modeled by Naïve Bayes Classifier
- How to deal with these dependencies? Bayesian Belief Networks (Chapter 9)

### Classification: Basic Concepts

- Classification: Basic Concepts
- Decision Tree Induction
- Bayes Classification Methods
- Model Evaluation and Selection
- Techniques to Improve Classification Accuracy: Ensemble Methods

### Model Evaluation and Selection

- Evaluation metrics: How can we measure accuracy? Other metrics to consider?
- Use validation test set of class-labeled tuples instead of training set when assessing accuracy
- Methods for estimating a classifier's accuracy:
  - Holdout method, random subsampling
  - Cross-validation
  - Bootstrap
- Comparing classifiers:
  - Confidence intervals
  - Cost-benefit analysis and ROC Curves

### Classifier Evaluation Metrics: Confusion Matrix

#### **Confusion Matrix:**

Actual class\Predicted class	$C_\mathtt{1}$	¬ C <sub>1</sub>
$C_\mathtt{1}$	True Positives (TP)	False Negatives (FN)
¬ C <sub>1</sub>	False Positives (FP)	True Negatives (TN)

#### **Example of Confusion Matrix:**

Actual class\Predicted class	buy_computer = yes	buy_computer = no	Total
buy_computer = yes	6954	46	7000
buy_computer = no	412	2588	3000
Total	7366	2634	10000

- Given m classes, an entry, CM<sub>i,j</sub> in a confusion matrix indicates # of tuples in class i that were labeled by the classifier as class j
  - May have extra rows/columns to provide totals

## Classifier Evaluation Metrics: Accuracy, Error Rate, Sensitivity and Specificity

Α\P	С	¬С	
С	TP	FN	Р
¬C	FP	TN	N
	P'	N'	All

 Classifier Accuracy, or recognition rate: percentage of test set tuples that are correctly classified

Accuracy = (TP + TN)/All

• **Error rate:** 1 – accuracy, or

Error rate = (FP + FN)/AII

#### Class Imbalance Problem:

- One class may be rare, e.g. fraud, or HIV-positive
- Significant majority of the negative class and minority of the positive class
- Sensitivity: True Positive recognition rate
  - Sensitivity = TP/P
- Specificity: True Negative recognition rate
  - Specificity = TN/N

# Classifier Evaluation Metrics: Precision and Recall, and F-measures

- **Precision**: exactness: what % of tuples that the classifier labeled as positive are actually positive  $precision = \frac{TP}{TP + FP}$
- Recall: completeness what % of positive tuples did the classifier label as positive?  $recall = \frac{TP}{TP + FN}$
- Comment:
  - Perfect score is 1.0
  - Inverse relationship between precision & recall
- F measure (or F-score): harmonic mean of precision and recall
  - In general, it is the weighted measure of precision & recall

$$F = \frac{1}{\alpha \cdot \frac{1}{P} + (1 - \alpha) \cdot \frac{1}{R}} = \frac{(\beta^2 + 1)PR}{\beta^2 P + R}$$
 Assigning  $\beta$  times as much weight to recall as to precision)

 F1-measure (balanced F-measure) » That is, when  $\beta = 1$ ,  $F_1 = \frac{2PR}{P+R}$ 

## Classifier Evaluation Metrics: Example

Actual Class\Predicted class	cancer = yes	cancer = no	Total	Recognition(%)
cancer = yes	90	210	300	30.00 (sensitivity)
cancer = no	140	9560	9700	98.56 (specificity)
Total	230	9770	10000	96.40 ( <i>accuracy</i> )

# Evaluating Classifier Accuracy: Holdout & Cross-Validation Methods

#### Holdout method

- Given data is randomly partitioned into two independent sets
  - Training set (e.g., 2/3) for model construction
  - Test set (e.g., 1/3) for accuracy estimation
- Random sampling: a variation of holdout
  - Repeat holdout k times, accuracy = avg. of the accuracies obtained
- **Cross-validation** (*k*-fold, where k = 10 is most popular)
  - Randomly partition the data into k mutually exclusive subsets, each approximately equal size
  - At i-th iteration, use D<sub>i</sub> as test set and others as training set
  - Leave-one-out: k folds where k = # of tuples, for small sized data
  - \*Stratified cross-validation\*: folds are stratified so that class dist. in each fold is approx. the same as that in the initial data

# Evaluating Classifier Accuracy: Bootstrap

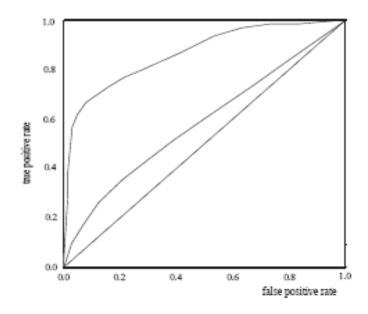

#### Bootstrap

- Works well with small data sets
- Samples the given training tuples uniformly with replacement
  - Each time a tuple is selected, it is equally likely to be selected again and re-added to the training set
- Several bootstrap methods, and a common one is .632 bootstrap
  - A data set with d tuples is sampled d times, with replacement, resulting in a training set of d samples. The data tuples that did not make it into the training set end up forming the test set. About 63.2% of the original data end up in the bootstrap, and the remaining 36.8% form the test set (since (1 − 1/d)<sup>d</sup> ≈ e<sup>-1</sup> = 0.368)
  - Repeat the sampling procedure k times, overall accuracy of the model:

$$Acc(M) = \frac{1}{k} \sum_{i=1}^{k} (0.632 \times Acc(M_i)_{test\_set} + 0.368 \times Acc(M_i)_{train\_set})$$

### Model Selection: ROC Curves

- ROC (Receiver Operating Characteristics) curves: for visual comparison of classification models
- Originated from signal detection theory
- Shows the trade-off between the true positive rate and the false positive rate
- The area under the ROC curve is a measure of the accuracy of the model
- Rank the test tuples in decreasing order: the one that is most likely to belong to the positive class appears at the top of the list
- The closer to the diagonal line (i.e., the closer the area is to 0.5), the less accurate is the model

- Vertical axis represents the true positive rate
- Horizontal axis rep. the false positive rate
- The plot also shows a diagonal line
- A model with perfect accuracy will have an area of 1.0

# Issues Affecting Model Selection

#### Accuracy

classifier accuracy: predicting class label

### Speed

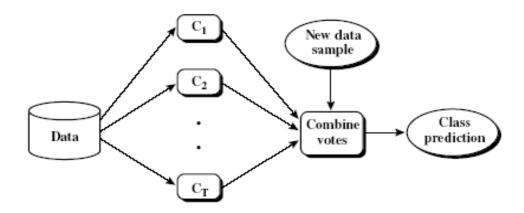

- time to construct the model (training time)
- time to use the model (classification/prediction time)
- Robustness: handling noise and missing values
- Scalability: efficiency in disk-resident databases
- Interpretability
  - understanding and insight provided by the model
- Other measures, e.g., goodness of rules, such as decision tree size or compactness of classification rules

## Classification: Basic Concepts

- Classification: Basic Concepts
- Decision Tree Induction
- Bayes Classification Methods
- Model Evaluation and Selection
- Techniques to Improve Classification Accuracy: Ensemble Methods

# Ensemble Methods: Increasing the Accuracy

- Ensemble methods
  - Use a combination of models to increase accuracy
  - Combine a series of k learned models, M<sub>1</sub>, M<sub>2</sub>, ..., M<sub>k</sub>, with the aim of creating an improved model M\*
- Popular ensemble methods
  - Bagging: averaging the prediction over a collection of classifiers
  - Boosting: weighted vote with a collection of classifiers
  - Ensemble: combining a set of heterogeneous classifiers

## Bagging: Boostrap Aggregation

- Analogy: Diagnosis based on multiple doctors' majority vote
- Training
  - Given a set D of d tuples, at each iteration i, a training set D<sub>i</sub> of d tuples is sampled with replacement from D (i.e., bootstrap)
  - A classifier model M<sub>i</sub> is learned for each training set D<sub>i</sub>
- Classification: classify an unknown sample X
  - Each classifier M<sub>i</sub> returns its class prediction
  - The bagged classifier M\* counts the votes and assigns the class with the most votes to X
- Prediction: can be applied to the prediction of continuous values by taking the average value of each prediction for a given test tuple
- Accuracy: Proved improved accuracy in prediction
  - Often significantly better than a single classifier derived from D
  - For noise data: not considerably worse, more robust

## Boosting

- Analogy: Consult several doctors, based on a combination of weighted diagnoses—weight assigned based on the previous diagnosis accuracy
- How boosting works?
  - Weights are assigned to each training tuple
  - A series of k classifiers is iteratively learned
  - After a classifier M<sub>i</sub> is learned, the weights are updated to allow the subsequent classifier, M<sub>i+1</sub>, to pay more attention to the training tuples that were misclassified by M<sub>i</sub>
  - The final M \* combines the votes of each individual classifier, where the weight of each classifier's vote is a function of its accuracy
- Boosting algorithm can be extended for numeric prediction
- Comparing with bagging: Boosting tends to have greater accuracy, but it also risks overfitting the model to misclassified data

## Adaboost (Freund and Schapire, 1997)

- Given a set of d class-labeled tuples,  $(X_1, y_1), ..., (X_d, y_d)$
- Initially, all the weights of tuples are set the same (1/d)
- Generate k classifiers in k rounds. At round i,
  - Tuples from D are sampled (with replacement) to form a training set D<sub>i</sub> of the same size
  - Each tuple's chance of being selected is based on its weight
  - A classification model M<sub>i</sub> is derived from D<sub>i</sub>
  - Its error rate is calculated using D<sub>i</sub> as a test set
  - If a tuple is misclassified, its weight is increased, o.w. it is decreased
- Error rate:  $err(\mathbf{X_j})$  is the misclassification error of tuple  $\mathbf{X_j}$ . Classifier  $M_i$  error rate is the sum of the weights of the misclassified tuples:  $error(M_i) = \sum_{j=1}^{d} w_j \times err(\mathbf{X_j})$
- The weight of classifier  $M_i$ 's vote is  $\log \frac{1 error(M_i)}{error(M_i)}$

## Random Forest (Breiman 2001)

#### Random Forest:

- Each classifier in the ensemble is a decision tree classifier and is generated using a random selection of attributes at each node to determine the split
- During classification, each tree votes and the most popular class is returned
- Two Methods to construct Random Forest:
  - Forest-RI (random input selection): Randomly select, at each node, F attributes as candidates for the split at the node. The CART methodology is used to grow the trees to maximum size
  - Forest-RC (random linear combinations): Creates new attributes (or features) that are a linear combination of the existing attributes (reduces the correlation between individual classifiers)
- Comparable in accuracy to Adaboost, but more robust to errors and outliers
- Insensitive to the number of attributes selected for consideration at each split, and faster than bagging or boosting

# Classification of Class-Imbalanced Data Sets

- Class-imbalance problem: Rare positive example but numerous negative ones, e.g., medical diagnosis, fraud, oilspill, fault, etc.
- Traditional methods assume a balanced distribution of classes and equal error costs: not suitable for classimbalanced data
- Typical methods in two-class classification:
  - Oversampling: re-sampling of data from positive class
  - Under-sampling: randomly eliminate tuples from negative class
  - Threshold-moving: move the decision threshold, t, so that the rare class tuples are easier to classify, and hence, less chance of costly false negative errors
  - Ensemble techniques: Ensemble multiple classifiers introduced above
- Still difficult for class imbalance problem on multiclass tasks

## Summary

- Classification: Extracting models describing important data classes
- Effective and scalable methods
  - Decision tree induction, Naive Bayesian classification, rule-based classification, and many other classification methods
- Evaluation metrics:
  - Accuracy, sensitivity, specificity, precision, recall, F measure, and  $F_{\beta}$  measure
  - Stratified k-fold cross-validation is recommended for accuracy estimation
- Ensemble: Bagging and boosting can be used to increase overall accuracy by learning and combining a series of individual models
- Model selection: Significance tests and ROC curves
- No single method has been found to be superior over all others for all data sets
